

In C

```
#include <stdio.h>
struct student {
    int Rollno;
    float marks;
    char name[50];
};
int main()
{
    printf("the size of the structure
    is ", sizeof(struct student), " bytes");
    return 0;
}
```

Output:-

the size of the structure
is 60 bytes

The size of is not same in Both case. Manually we allocate memory as per particular bytes. But in compile based programme some memory is added by the compiler. It means padding of memory by the compiler. for extra we.

```
#include <iostream>
using namespace std;
struct student {
    int rollno;
    float marks;
    char name[50];
};
int main()
{
    cout << "the size of the
    structure " << sizeof(struct
    student) << " bytes";
    return 0;
}
```

Output:-

the size of the structure
is 60 bytes
